

php code for inheritance

Topics : [PHP Programs](#)

Written on [December 13, 2022](#)

A extends keyword can be used for inheritance.

Example :

```
<?
class A
{
    static $k=400;
    function A()
    {

        $this->i=100;
        self::$k=500;
    }
    function display()
    {
        echo "<br/>Inside parent class!!";
        echo "<br/> parent class K: ".self::$k;
    }
}

class B extends A
{
    function show()
    {
        echo "<br/> from subclass k : ".parent::$k;
    }
}

$objb = new B();

$objb->display();

echo "<br/> I : ".$objb->i;
```

```
echo "<br/> k :".$objb->show();  
echo "<br/> Out side class K: ".A::$k;  
  
?>
```

Output :

```
Inside parent class!!  
parent class K: 500  
I :100  
from subclass k : 500  
k :  
Out side class K: 500
```
