

# C Function Declaration

Topics : [C](#)

Written on [April 13, 2023](#)

In C programming language, a function is a block of code that performs a specific task and can be called from other parts of the program. Functions provide modularity and reusability to programs, and make them easier to read, test, and maintain.

A function in C typically consists of the following parts:

1. Function header: specifies the function name, return type, and parameter list.
2. Function body: contains the statements that define what the function does.
3. Function call: invokes the function from within another part of the program.

The syntax for defining a function in C is as follows:

```
return_type function_name(parameter1_type parameter1, parameter2_type  
parameter2, ...) {  
    // function body  
    return return_value; // optional  
}
```

where:

- **return\_type**: specifies the data type of the value that the function returns (such as `int`, `float`, `void`, etc.).
- **function\_name**: specifies the name of the function (must be a valid identifier in C).
- **parameter1\_type**, **parameter2\_type**, etc.: specify the data types of the parameters that the function expects to receive (such as `int`, `float`, `char`, etc.).
- **parameter1**, **parameter2**, etc.: specify the names of the parameters.
- **return\_value**: specifies the value that the function returns (if the `return_type` is not `void`).

For example, the following is a definition of a function named `sum` that takes two integer parameters and returns their sum:

```
int sum(int a, int b) {  
    int result = a + b;  
    return result;
```

}

This defines a function named `sum` that takes two integer parameters named `a` and `b`, adds them together, stores the result in a variable named `result`, and returns the value of `result`. To call this function from within another part of the program, we can use the following syntax:

```
int x = 5;  
int y = 7;  
int z = sum(x, y); // z will be assigned the value 12
```
